The book that helped make Michael Pollan, the New York Times bestselling author of *How to Change Your Mind*, *Cooked* and *The Omnivore's Dilemma*, one of the most trusted food experts in America. Every schoolchild learns about the mutually beneficial dance of honeybees and flowers: The bee collects nectar and pollen to make honey and, in the process, spreads the flowers' genes far and wide. In *The Botany of Desire*, Michael Pollan ingeniously demonstrates how people and domesticated plants have formed a similarly reciprocal relationship. He masterfully links four fundamental human desires—sweetness, beauty, intoxication, and control—with the plants that satisfy them: the apple, the tulip, marijuana, and the potato. In telling the stories of four familiar species, Pollan illustrates how the plants have evolved to satisfy humankind's most basic yearnings. And just as we've benefited from these plants, we have also done well by them. So who is really domesticating whom?

Although it is possible to breed Cannabis with limited knowledge with the help of laws of inheritance, the full benefits of diligent breeding, and the line of action most likely to lead to the best results, are realized by breeders who have more advanced working knowledge of genetics. As we know already, all forms of Cannabis are produced from generation to generation by the fusion of the staminate and the pistillate forms. From the two sets of chromosomes, a seed forms, and a new Cannabis plant is born. Both pollen and ovules are known to be transmitted units determining the expression of a particular trait known as a gene. Individual plants have two different sets of chromosomes (2n) in every cell except the gametes, which through reproduction have only one set of genes (n). Unlike the two sets from which the embryo is formed (2n). In Cannabis, the haploid (n) number of chromosomes is 10 and the diploid (2n) number of chromosomes is 20. Each chromosome contains hundreds of genes, influencing various aspects of the growth and development of the plant. If two plants of the same genetic trait (or self-pollination of a hermaphrodite) result in offspring that all exhibit the same trait, and if all subsequent generations exhibit the same trait, then we say that the trait is true-breeding, or breeds true, for that trait. A strain may be true for one or more traits while exhibiting other characteristics. For example, the trait of being true for a particular trait, while exhibiting other traits in a strain to be true for a trait, both of the gametes forming the offspring are identical complement of the genes that influence that particular trait. For example, a plant that breeds true for webbed leaves, any gamete from that plant in that cell will contain the gene for webbed leaves, which we will signify with the letter w. Since each gamete carries one-half (n) of the genetic complement of the offspring, it follows that upon fertilization both "half genes" of the (2n) offspring will be w. That is, the offspring will be true-breeding for webbed leaves because they have two w genes to work on in the gametes.
